## QUESTION 1

We ran the following regression model:

$$RL(ID) = \beta_0 + \beta_1 trend + u(ID),$$

where  $u(ID)$  is a random error.

The results are shown below:

```
Call:
lm(formula = road_sum ~ trend, data = df)

Residuals:
    Min       1Q   Median       3Q      Max
-115.0   -93.4   -55.4    25.6   3932.9

Coefficients:
              Estimate Std. Error t value Pr(>|t|)
(Intercept)  107.835     8.156   13.221  <2e-16 ***
trend         1.071     1.613    0.664    0.507
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 186.4 on 2122 degrees of freedom
(301 observations deleted due to missingness)
Multiple R-squared:  0.0002077, Adjusted R-squared:  -0.0002635
F-statistic: 0.4408 on 1 and 2122 DF,  p-value: 0.5068
```

# INTERPRETATION

$\beta_0$  represents the road length when trend = 0, which has come out to be ~ 107.83 kms.

$\beta_1$  represents the avg change in road length (in km) due to a unit increase in trend (i.e when moving from any one year to the next).

Thus, between the years 2011-2021, the road length increased on avg ~ 1.07 kilometres each year

$\beta_0$  -> the intercept

$\beta_1$  -> the slope

RL -> Response variable

trend -> predictor variable

### QUESTION 3

We ran the following regression model:

$$RL(ID) = \gamma_0 + \gamma_1 D_{South} + \varepsilon(ID),$$

where  $\varepsilon(ID)$  is a random error.

The results are shown below:

```
> summary(road_lm_DSouth)

Call:
lm(formula = road_sum ~ DSouth, data = df)

Residuals:
    Min       1Q   Median       3Q      Max
-117.8   -94.6   -48.7    27.0   3930.9

Coefficients:
            Estimate Std. Error t value Pr(>|t|)
(Intercept)  118.363     4.229   27.99  < 2e-16 ***
DSouth       -62.179    13.817   -4.50 7.16e-06 ***
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 185.6 on 2122 degrees of freedom
(301 observations deleted due to missingness)
Multiple R-squared:  0.009453, Adjusted R-squared:  0.008986
F-statistic: 20.25 on 1 and 2122 DF, p-value: 7.158e-06
```

The model is a linear regression of road length (in kilometers) on the dummy variable DSouth, which takes the value 1 if the district belongs to any of the following states: Andhra Pradesh, Tamil Nadu, Kerala, or Telangana, and 0 otherwise.

## INTERPRETATION

$\gamma_0$  represents the road length when DSouth = 0, which has come out to be ~ 118.36 kms.

$\gamma_1$  is the slope, is equal to ~ -62.18kms, which means that when DSouth is equal to 1 (i.e., when the district is in the southern states), the expected road length is ~62.18 kilometers LESS than when DSouth is equal to 0 (i.e., when the district is not in the southern states).

$\gamma_0$  -> the intercept

$\gamma_1$  -> the slope

RL -> Response variable

DSouth -> predictor variable

## QUESTION 4

We ran the following regression model:

$$RL(ID) = \eta_0 + \eta_1 D_{South} + \eta_2 D_{North} + \eta_3 D_{East} + \eta_4 D_{West} + \theta(ID),$$

where  $\theta(ID)$  is a random error.

The results are shown below:

```
Call:
lm(formula = road_sum ~ DSouth + DNorth + DEast + DWest, data = df)

Residuals:
    Min       1Q   Median       3Q      Max
-149.0   -87.3   -43.6    24.2   3950.2

Coefficients:
              Estimate Std. Error t value Pr(>|t|)
(Intercept)    99.119      6.004   16.509  < 2e-16 ***
DSouth        -42.935     14.339   -2.994  0.00278 **
DNorth         43.658     11.194    3.900  9.92e-05 ***
DEast          51.298     10.168    5.045  4.93e-07 ***
DWest         -46.897     18.514   -2.533  0.01138 *
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 183.7 on 2119 degrees of freedom
(301 observations deleted due to missingness)
Multiple R-squared:  0.03071,    Adjusted R-squared:  0.02888
F-statistic: 16.78 on 4 and 2119 DF,  p-value: 1.492e-13
```

The model predicts the road sum based on the district belonging to any of the south, north, east, or west regions. The coefficients indicate the average effect on the road sum of belonging to any of the respective regions, while holding other factors constant

# INTERPRETATION

$\eta_0$ , The intercept of ~99.12 kms represents the estimated average road sum for districts that do not belong to any of the four regions.

$\eta_1$ , the coefficient of ~ -42.94 for DSouth indicates that the mean outcome variable for districts in the southern region (represented by DSouth=1) is estimated to be 42.94 km lower than the mean outcome for the reference region (represented by DSouth=0) while holding all other variables constant.

$\eta_0$  -> the intercept term

$\eta_1$  -> the coefficient of DSouth

$\eta_2$  -> the coeff. of DNorth

$\eta_3$  -> the coeff. of DEast

$\eta_4$  -> the coeff. of DWest

# INTERPRETATION (CONTD)

$\eta_2$ , the coefficient of  $\sim 43.66$  for  $DNouth$  indicates that the mean outcome variable for districts in the Northern region (represented by  $DNorth = 1$ ) is estimated to be  $\sim 43.66$  km higher than the mean outcome for the reference region (represented by  $DNorth=0$ ) while holding all other variables constant.

$\eta_3$ , the coefficient of  $\sim 51.3$  for  $DEast$  indicates that the mean outcome variable for districts in the eastern region (represented by  $DEast = 1$ ) is estimated to be  $\sim 51.3$  km higher than the mean outcome for the reference region (represented by  $DEast = 0$ ) while holding all other variables constant.

$\eta_4$ , the coefficient of  $\sim -46.9$  for  $DWest$  indicates that the mean outcome variable for districts in the western region (represented by  $DWest = 1$ ) is estimated to be  $\sim 46.9$  km lower than the mean outcome for the reference region (represented by  $DWest = 0$ ) while holding all other variables constant.

**NOTE:** In this model with four dummy variables representing different regions of a country and a continuous outcome variable, the coefficients represent the difference in the mean outcome between the reference region (not included as a dummy variable, i.e **DCentre** in our case) and each of the other regions, while holding all other variables constant.

## QUESTION 5

We ran the following regression model:

$$RL(ID) = \alpha_0 + \alpha_1 \text{trend} + \alpha_2 \text{DSouth} + \alpha_3 \text{DSouth} * \text{trend} + \delta(ID),$$

where  $\delta(ID)$  is a random error.

The results are shown below:

```
Call:
lm(formula = road_sum ~ trend + DSouth + (DSouth * trend), data = df)

Residuals:
    Min       1Q   Median       3Q      Max
-127.2   -94.0   -45.6    25.1   3920.7

Coefficients:
            Estimate Std. Error t value Pr(>|t|)
(Intercept)   106.350      8.404   12.654  <2e-16 ***
trend           2.779      1.681    1.653   0.0984 .
DSouth         2.341     32.287    0.073   0.9422
trend:DSouth  -13.187      5.850   -2.254   0.0243 *
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 185.4 on 2120 degrees of freedom
(301 observations deleted due to missingness)
Multiple R-squared:  0.01233,    Adjusted R-squared:  0.01094
F-statistic: 8.825 on 3 and 2120 DF,  p-value: 8.183e-06
```

The above model is a multiple linear regression model that aims to explain the variation in the dependent variable "road\_sum" based on three independent variables: "trend", "DSouth", and the interaction between "trend" and "DSouth".

# INTERPRETATION

The intercept ( $\alpha_0$ ) is 106.350, which means that when trend and DSouth are equal to zero, the estimated mean of road\_sum is 106.350 km.

The coefficient estimate for the trend variable ( $\alpha_1$ ) is 2.779, which means that on average, for each unit increase in the trend, the estimated mean of road\_sum increases by 2.779, holding DSouth constant.

$\alpha_0$  -> the intercept term

$\alpha_1$  -> the coefficient of trend

$\alpha_2$  -> the coeff. of DSouth

$\alpha_3$  -> the coeff. of (trend\*DSouth), it captures the interaction effect between trend and DSouth.

# INTERPRETATION (CONTD)

The coefficient estimate for the DSouth ( $\alpha_2$ ) is  $\sim 2.34$ , which means that, on average, the estimated mean of road\_sum is 2.341 km higher for roads in the southern region, holding the trend (i.e. year) constant.

The coefficient estimate for the interaction between trend and DSouth ( $\alpha_3$ ) is  $\sim -13.19$ , which means that the effect of trend on road\_sum is different for roads in the southern region than for roads in other regions. In particular, for each unit increase in the trend, the estimated mean of road\_sum decreases by 13.19 km for roads in the southern region.
